What, and how, children eat can affect their mood, behaviour and learning. The best diet for good mood, behaviour and learning is one that includes a regular eating pattern and a variety of food.

**Eating a varied diet**

We need many different nutrients in our diet to support our brain. These include vitamins, essential fats and amino acids (found in protein). The best way to get them is by eating a varied diet.

A large, well designed, study of adolescents showed that “healthier” dietary patterns contributed to better mood, and “unhealthy” dietary patterns lead to poor mood. The same study was able to show that poor mood did not cause an unhealthy dietary pattern.

**Eating regular meals**

Eating regular meals helps to regulate blood sugar. This may influence some of the hormones that control our mood and ability to concentrate. For this reason, poor mood and behaviour are often observed in children who have been without food for too long (for example, children who haven’t eaten breakfast).

**The importance of specific nutrients for the brain**

Some nutrients seem to be particularly important for the brain. These include minerals like Iron, Zinc, Magnesium and Iodine; Vitamin D; B vitamins and omega 3 fatty acids. In addition, dietary fibre from plant-based foods may also be important.

**Studies of Single Nutrients**

Studies using individual nutrients to improve mood, behaviour or learning in children often produce disappointing results. This is probably because nutrients work together rather than alone.

**Vitamin D and Omega 3**

There is some evidence that Vitamin D and Omega 3 supplements can help with mood or attention in some vulnerable children. This is not surprising because both children and adults in the UK often have low levels of these nutrients.

Omega 3 supplements may improve attention in ADHD and irritability in Autism. There is some evidence that Omega 3 can improve mood and reduce anxiety in people with those difficulties, but this evidence is mostly from studies with adults.

Vitamin D may help reduce irritability and hyperactivity in children with Autism. It may also improve inattention in children with ADHD, especially if they are deficient.

The best ways to get enough of Vitamin D is to expose the skin to sunlight in the summer months (without burning). Most children would benefit from a Vitamin D supplement.

**Dietary sources of important nutrients for the brain**

Oily fish is a good source of omega 3. Current dietary advice on fish is to include two portions each week, including at least one portion of oily fish (such as sardines, herring, mackerel or salmon). Seafood is rich in other nutrients too. For children who do not eat fish, Omega 3 can be found in walnuts, flaxseeds, chia seeds, leafy green vegetables and rapeseed oil.

Red meat is a good source of Iron and Zinc, however **too much red meat is not recommended**. Instead sources of Iron and Zinc can also be found in pulses, nuts, beans, green vegetables, bread and breakfast cereals.

Green vegetables are a good source of magnesium.

Fish, milk, yoghurt and eggs are a good source of iodine.

“Multi-nutrient” Supplements
In theory, any child who is struggling to eat a varied diet, could benefit from a multi-nutrient supplement giving a wide range of vitamins and minerals. There is some evidence that children with ADHD, in particular, might benefit from this kind of supplement.

**The Importance of Dietary Fibre for Mood and Learning**

It is well known that fibre is important for gut health. It also seems to help regulate blood sugar, which may help with mood and attention.

The positive effects on mood and attention of eating a meal, may last for a shorter time if there is less fibre. This may be why children have been shown to perform better in tests of attention and memory, two hours after a high fibre breakfast cereal, when compared to a high sugar, low fibre one.

Dietary fibre and some fermented foods (like live yoghurt) may also promote a healthy “microbiome” (the name given to the billions of micro-organisms living in our gut). This may, in turn, also contribute to good mood and general wellbeing, in ways that are not yet fully understood.

**Dietary Sources of Fibre**

Most plant-based foods contain dietary fibre. Examples include, fruits, vegetables, wholegrain cereals, beans, nuts and pulses. However, sometimes the fibre is removed or reduced during food processing (for example in white bread, fruit juice and some breakfast cereals).

**What does an adequate and varied diet look like?**

For most children over 2 years of age (and adults), if they are including a variety of foods from each of the “Food Groups” of the Eatwell Guide on a daily basis, they are likely to be getting most of what they need. Insert picture of Eatwell Guide below:

**Food intolerance**

Some children have food intolerance(s) which can mean that their mood or behaviour are affected by specific foods or ingredients. These can produce physical symptoms too.

If you believe your child may have a food intolerance, you should discuss your concerns with your GP or dietitian. They may recommend an “exclusion diet” – where the food is completely removed from your child’s diet and later re-introduced it to see if there is a consistent impact on mood or behaviour.

**Top tips**
- Eating a wide variety of nutritious foods helps mood, attention and learning.
- Eating regular meals also helps promote good mood and attention.
- Including foods that are rich in dietary fibre may also help.
- Nutritional supplements may help some children. This is especially true when the diet is low in any particular nutrients.

A dietitian is uniquely qualified to provide an accurate assessment of the diet and any risk of deficiency. They can also provide practical advice on the best way to improve nutrition through changes to the diet, nutritional supplements or both.
